

Reunion Gold announces a significant resource estimate for its Matthews Ridge Manganese Project

Longueuil, Canada, February 21, 2013. Reunion Gold Corporation (TSX-V: RGD) (“Reunion or the “Company”) is pleased to announce an initial resource estimate for the manganese deposits of its 100%-owned Matthews Ridge Project in northwest Guyana, South America.

Highlights:

- Total Unconstrained Measured and Indicated Resources of 32.4M tonnes grading 14% Mn when using an 8% Mn cutoff grade on the footprint of Matthew’s Ridge.
- Additional 5.3 M tonnes of Unconstrained Inferred Resources grading 15% Mn at an 8% Mn cutoff grade on the Matthew’s Ridge Footprint and from two other prospects.
- Total Constrained Measured and Indicated Resources of 29.1M tonnes grading 14% Mn at a cutoff grade of 6-8% Mn.
- Robust resource model as demonstrated by a 90% conversion rate of the measured and indicated resources from Unconstrained to Constrained Resources.
- Metallurgical testwork indicates good manganese recovery to concentrates of marketable quality.

Table 1: Unconstrained Mineral Resource Summary at an 8% Mn cut off grade

	Unconstrained (see notes below Table 8)							
	Measured		Indicated		Total M&I		Inferred	
	'000 t	% Mn	'000 t	% Mn	'000 t	% Mn	'000 t	% Mn
Matthew’s Ridge	16,987	14	15,388	13	32,375	14	3,368	15
Arakaka prospect	-	-	-	-	-	-	168	13
Pipiani prospect	-	-	-	-	-	-	1,756	15
Total	16,987	14	15,388	13	32,375	14	5,292	15

Table 2: Constrained Mineral Resource Summary

	Constrained (see notes below Table 8)*							
	Measured		Indicated		Total M&I		Inferred	
	'000 t	% Mn	'000 t	% Mn	'000 t	% Mn	'000 t	% Mn
Matthew’s Ridge (Hills 1 – 9)	15,655	15	13,508	13	29,163	14	2,786	16
Total	15,655	15	13,508	13	29,163	14	2,786	16

*Cut off varies by hill and material type between 6 and 8% for constrained resources.

Other Project Highlights:

- Located in Guyana, a mining friendly jurisdiction;
- Low level of infrastructure requirements;
- Simple open pit mining and processing operation;
- The defined resources are of sufficient scale and quality to form the foundation of the ongoing pre-feasibility study to define the economics of project development;
- Four other prospects in the Matthews Ridge region are being explored for additional resources;
- Reunion holds exploration licenses for an area of 185 square kilometers in northwest Guyana.

Resource Estimate

This first Matthews Ridge mineral resources estimate was prepared by Mr. Réjean Sirois, ing., P. Geo., of G Mining Services Ltd. (“GMining”), a Canadian mining consulting firm, for the four types of mineralized materials forming the deposits (defined in Appendix 1). It encompasses over 65 thousand metres of drilling completed by Reunion between 2011 and 2012. The resources have been categorized as measured, indicated or inferred. They have been estimated on an unconstrained basis, as well as, on a constrained basis in a Whittle shell with the utilisation of metallurgical, economical and geotechnical constraints. The results are tabulated below. See Appendix 1 for additional information on parameters and methodology used for resource estimates. (link to Appendix 1)

6%	1,914	14	344	37	127	35	471

Notes:

1. The effective date of the mineral resource estimate is February 20, 2013.
2. Unconstrained resources mean total in-situ resources.
3. Constrained resources mean resources contained within a Whittle shell when applying industry standard parameters for costs, geotechnical constraints, metallurgical recoveries and indicative value of the final product. The cut-off grade varies by hill and material type and is generally between 6% and 8%.
4. Lump Product is defined as material from +6mm to -25mm in size while Fine Product is +0.85mm to 6mm in size.
5. Mineral resources, which are not mineral reserves, do not have demonstrated economic viability. The estimate of mineral resources may be affected by marketing, fiscal, permitting, legal, or other relevant issues.
6. Totals and average grades are subject to rounding to the appropriate precision.

David Fennell, Executive Chairman of Reunion, said: “This is a tremendous accomplishment for Reunion’s team. Since obtaining the prospecting licenses for Matthews Ridge in late 2010, our team has embarked on an extensive drilling campaign to establish an initial resource estimate and move Matthews Ridge towards development. We believe that the Matthews Ridge project has the potential to become a leading producer of manganese in the Americas. While this resource is very substantial, many undrilled targets remain available for additional resource growth.”

General Project Description

The Matthews Ridge Project consists of four Prospecting Licenses covering an area of 185 km² located in northwest Guyana, in and around the former Matthews Ridge mine (See maps - Figure 1 and 2). Manganese ore was mined from 1960 to 1968 by a subsidiary of Union Carbide and exported via railroad and a fluvial port.

Manganese deposits have been explored in three prospects: 1) Matthews Ridge, corresponding to a series of nine hills extending for 15 km, of which five were previously mined; 2) Arakaka, which is the eastern extension of Hill 1, and 3) Pipiani, which is located 65 km to the southeast of Matthews Ridge.

Manganese mineralization is hosted by the Barama Group sedimentary rocks of Proterozoic age and consists of deposits formed as a result of supergene enrichment of manganese-rich sediments under a tropical climate.

Metallurgical Testing

As part of the metallurgical testing of mineralized materials, representative samples of each material type were processed by scrubbing, wet screening and jigging with an AlljigTM lab-scale jig operated by FILAB Guyana Laboratories under the supervision of GMining. Core samples were split with one portion of the sample being placed into a composite sample of similar material and processed by jigging while the remaining portion was sent to SGS Lakefield in Canada for metallurgical characterization through heavy liquid separation (HLS). GMining supervised all work performed by SGS. HLS results were correlated to the composite jigging results.

Based on the metallurgical testwork and characterization by material type, a relationship was established between the feed grade of the material and its potential upgradability. This was done by associating the feed grade of the material, the concentrate recovery and the concentrate grade while applying minimum concentrate grade requirements set at 36% and 34% Mn, respectively, for the Lump and Fine products.

GMining concluded that the Matthew’s Ridge ore is upgradable to a marketable concentrate. (see Reunion’s August 27, 2012 news release). Two distinct types of marketable concentrate can be produced. A higher valued Lump Concentrate (-25 mm + 6 mm) and a lower valued Fine Concentrate (-6 mm + 0.85 mm). The Lump product represents approximately 62% of the total concentrate while the Fine product represents 38% of the total when constrained within a Whittle shell.

The metallurgical testwork also tracked the level of impurities in the feed and in the different concentrates. It is noted that the level of silica and alumina decrease by half while the concentration of iron doubles as a result of jigging. The level of phosphorous remains relatively unchanged, at very low levels. All average impurity levels are within current industry benchmark values for similar concentrates destined to silica-manganese furnaces.

Table 9: Average Resource Impurity Concentrations by Product Size.

Impurity	Range (%)	
	Lump	Fine
SiO ₂	19-23	23-25
Al ₂ O ₃	8-9	9-11
Fe	4.5-6*	4.5-6*
P	0.05-0.06	0.05-0.06
LOI	12-13	12-14

*Higher grade Fe contents (up to 11%) are observed in detrital material concentrates

Grade and Tonnage Reporting

The Matthews Ridge mineral resource was estimated using the Canadian Institute of Mining, Metallurgy and Petroleum (CIM), CIM Standards on Mineral Resources and Reserves, Definitions and Guidelines prepared by the CIM Standing Committee on Reserve Definitions and adopted by CIM Council.

The resource model has been categorized as Measured, Indicated and Inferred Resources using the CIM Standards on Mineral Resources and Reserves, Definitions and Guidelines (November 2010).

Plans for 2013

The defined resources reported here provide a platform for Reunion to advance the Matthews Ridge Manganese Project through feasibility. Subject to available financing, the Company's plan for 2013 would be to complete an aggressive resource definition program on the Pipiani and Arakaka prospects, upgrade the inferred resources of the Matthew's Ridge trend and complete a pre-feasibility study.

Qualified Persons

The exploration data used to generate the resource estimates contained in this press release was approved by Carlos H. Bertoni, P. Geo., a consultant to the Company. Mr. Bertoni is an independent 'qualified person' within the meaning of that term under Canadian National Instrument 43-101 ("NI 43-101").

The Matthews Ridge resource estimates reported in this news release were undertaken by Mr. Réjean Sirois, ing., P. Geo., of GMining. Mr. Sirois is an independent 'qualified person' within the meaning of that term under NI 43-101. Mr. Sirois has reviewed and approved the contents of this press release insofar as the Matthews Ridge mineral resource estimate is concerned.

Mr. Ahmed Bouajila, ing., of GMining has supervised the metallurgical testing described in this news release. Mr. Bouajila is an independent 'qualified person' within the meaning of that term under NI 43-101. Mr. Bouajila has reviewed and approved the contents of this press release insofar as the Matthews Ridge metallurgical testwork is concerned.

All other technical information contained in this press release was prepared and approved by Mathieu Gignac ing., of GMining. Mr Gignac is an independent 'qualified person' within the meaning of that term under NI 43-101.

A technical report for the mineral resource estimate in compliance with NI 43-101 will be filed on SEDAR within 45 days of this press release.

About the Company

Reunion Gold Corporation is a mineral exploration company focused on the acquisition, exploration and development of mineral properties in the Guyana Shield of South America. The Company through its 100% indirectly owned subsidiary Reunion Manganese Inc., has assembled a large, strategic land position to conduct exploration and development activities for manganese in the North West District of Guyana. The Company also has the right to acquire a 100% interest in a gold exploration project located in the Lely Mountain area in Eastern Suriname.

Manganese is the fourth largest metal consumed in the world, behind iron, aluminum and copper. It is a key component in steel and iron production with no viable substitute.

Additional information about the Company is available on SEDAR at www.sedar.com and at www.reuniongold.com.

Forward Looking Statements

This press release contains forward-looking information. Although the Company believes in light of the experience of its officers and directors, current conditions and expected future developments and other factors that have been considered appropriate that the expectations reflected in this forward-looking information are reasonable, undue reliance should not be placed on them because the Company can give no assurance that they will prove to be correct. Forward looking information in this news release includes statements with respect to: the mineral resource estimates and potential expansion and upgrade to a higher level of confidence; the results of metallurgical testwork; the potential to develop the project into a mine and becoming a leading producer of manganese; and statements about the Company's plan and objectives for 2013. Forward-looking information involves known and unknown risks, uncertainties, assumptions and other factors that may cause actual results or events to differ materially from those anticipated in such forward-looking information. The forward-looking statements contained in this press release are made as of the date hereof and the Company undertakes no obligations to update publicly or revise any forward-looking statements or information, whether as a result of new information, future events or otherwise, unless so required by applicable securities laws.

Neither the TSX Venture Exchange nor its Regulation Services Provider (as that term is defined in the policies of the TSX Venture Exchange) accepts responsibility for the adequacy or accuracy of this press release.

Appendix 1

Parameters and methodology used for resource estimates

Mineralized material

The mineralized materials forming this resource include a combination of material from tailings, detritic deposits, saprolite deposits, and transition material, which are described below:

- **Tailings:**

The previous mining of manganese ore at Matthews Ridge produced a significant volume of washplant reject material (tailings), which did not meet commercial specifications at the time, but that was conveniently deposited next to the processing plant in a shallow valley. The Company drilled this material with 119 holes using a manual Banka and collected 208 samples.

- **Detrital:**

The detrital deposits are characterized by fairly loose manganese-rich nodules and fragments forming blankets covering hills with subjacent saprolitic mineralization and easily extractable by free digging. The Company sampled this material with 365 pits along the Matthews Ridge prospect (Hills 1 to 9) area, 182 pits at the Arakaka prospect and 351 pits at the Pipiani prospect.

- **Saprolite:**

The saprolite deposits are formed by manganese oxide and hydroxide minerals occurring in clastic sediments that were thoroughly weathered and occur along the crest of hills as the main components of the lateritic profile. This mineralized material was sampled in the Matthews Ridge prospect (Hills 1 to 9) area by 142 trenches, 47,570 meters of diamond drilling in 735 holes, and 17,361 meters of reverse circulation drilling in 283 holes. Trenches, drill holes and pit collars were surveyed by independent surveyors and diamond drill holes were down-hole surveyed, on average, every 30 meters using electronic survey equipment. The Matthews Ridge prospect (Hills 1 to 9) area has been drilled on a nominal 50 meter by 50 meter grid spacing.

- **Transition:**

The so-called transition material consists of mineralized saprolite at the transition to fresh rock, where the manganese-bearing sediments are incompletely weathered. This material was sampled by diamond and reverse circulation drilling only.

Sampling

Trench sampling was conducted as channels on the wall just above the trench floor on one meter intervals. Diamond drilling was done using HQ-diameter casing and triple-tube core barrel to maximize recovery. Half of the core was used for sampling at regular 1.5 m intervals. Reverse circulation drilling was done with four-inch casing, sampling at every meter and splitting the rock chips once in the field and processing an entire half sample. Banka drilling of tailings was done with six-inch casing and sampling at every meter. Detrital material was sampled from pits and trenches with 30 cm-wide vertical channels.

Assaying, Quality Assurance and Quality Control

Standard reference materials, internal standards, blanks and duplicate samples have been used to control laboratory accuracy and precision. Drill core sample preparation was done by Activation Laboratories Ltd. and ACME Laboratories at their facilities in Georgetown. It comprised of crushing to minus 2 mm and pulverization passing

200 mesh, followed by XRF assays for manganese and other relevant oxides at their laboratories in Canada. Sample preparation and XRF assay of reverse circulation drill and detrital samples were done by FILAB Guyana Laboratories on site using the same methodology described above.

Density Measurements

Density measurements were routinely taken from diamond drill core on samples spaced at approximately four meters down hole. The “wet” and “dry” densities of the drill core segments were measured using the industry-standard hydrostatic method, but only the dry density values (with measurement of water loss in oven) were used for the resource estimate. The densities of tailings and detritic materials were measured using a bulk technique by digging small pits on representative occurrences of these materials.

Resource and Grade Modeling

The geological units were interpreted on sections by Reunion Manganese personnel. GMining Services validated the interpretation and created 3D geological envelopes that were used to constrain the grade estimation during the interpolation process. Resource estimation was completed using the geostatistical estimation technique, called Ordinary Kriging (“OK”). Validation of the estimated manganese grades and other elements such as SiO₂, Al₂O₃, P and Fe were performed on cross-sections and plan views.

Variography and Grade Capping

The continuity in three dimensions of the various grade elements was studied using the Correlograms technique. Parameters were defined for each unit according to the material types and applied to each element during the estimation process. Hard boundary technique was used to avoid unnecessary grade smearing during interpolation. Statistical analysis was performed on all the elements. All the populations follow a log-normal distribution and a high grade limit of 30% Mn was used to avoid smearing of the high grade values.

Parameters Utilized to Estimate Constrained Resources

A number of industry standard and benchmark values were utilized in order to constrain the Matthew’s Ridge prospect (Hills 1 to 9) resources to a Whittle shell. Resources from Arakaka and Pipiani prospects have not been evaluated. The main input parameters for operating costs and concentrate pricing include:

Costs		
Mining	2.00	\$/t mined
Processing and Power	3.00	\$/t milled
G&A	5.00	\$/t milled
Concentrate Transportation	30.00	\$/t moved
Concentrate Pricing (FOB Guyana)		
Lump 40%	4.38	\$/dmu
Lump 38%	4.18	\$/dmu
Fine 40%	3.32	\$/dmu
Fine 38%	3.12	\$/dmu
Fine 36%	2.92	\$/dmu

Other inputs include the metallurgical equations by material type as generated by the metallurgical testwork. The cut-off grades utilized vary by hill and material type and are generally between 6% and 8%. The cut off grades are generally defined by the upgradability of the material, meaning that below 6 to 8%, it was impossible to upgrade the material to a marketable concentrate grade.
